

**The Great Trees
Of Oklahoma
2014 Registry**

- Champion Black Walnut -

You may have a champion in your front yard!

Since the early 1960's the Oklahoma Forestry Association, in cooperation with Oklahoma Forestry Services, has searched out and recorded the largest trees of each species occurring in the state. The list has been updated and published periodically ever since. Currently, there are close to 100 champion and co-champion trees listed.

The Oklahoma champion tree list has broad appeal. Many homeowners take great pride in having the largest specimen of a particular tree species in their yard. The Oklahoma champions are also submitted to the American Forestry Association to be recorded nationally. Oklahoma's Champion Black Hickory is currently recognized as being the largest tree of its species in the entire United States!

You can play a critical role in the future of Oklahoma's great trees. By nominating new great trees, by planting tomorrow's great trees, and conserving trees, you help to ensure that Oklahoma continues its rich forest heritage.

Application forms and detailed measurement instructions to nominate your Great Tree are available at:

How to Measure a Champion Tree

The size of a champion tree is calculated using a point system developed by American Forests (www.americanforests.org). A champion's point total is a composite of its circumference, its total height and one quarter of its average crown spread.

Measuring Circumference

Circumference is a measure of the distance, in inches, around the tree using an ordinary tape measure. On level ground, this measurement is taken at 4.5 feet above the ground. Trees with an obstruction at 4.5 feet, such as a knot, should be measured above and below the obstruction and the smallest measurement recorded along with the height of this measurement.

Tree on a Slope: On a slope, the measurement is taken at both the high and low sides and averaged. The same goes for a tree that is growing at an angle.

Forked Tree: Take the measurement at the smallest point, below the lowest fork, between 4.5 ft and the ground, excluding dead branches and epicormic sprouts; also record the height at which the measurement was taken.

One Tree vs. Multiple Trees: Trunks that have clear separation at or near the ground should be considered separate trees and measured accordingly. Also if the circumference measurement below the lowest fork places the measurement at the ground, it should be considered separate trees.

Measuring Average Crown Spread

Average crown spread is measured in feet and is the average of the greatest and least distance across the drip line of the tree. This measurement is often the least accurate, due to the subjective nature of the exact points to be measured. Once the widest and narrowest distances are determined, they are added together and divided by 2.

Measuring Total Tree Height

There are many tools that can be used to estimate the height of a tree including something as simple as a stick, but if at all possible height measurements should be confirmed by an expert such as a local arborist or forester. The vertical height of a tree is measured in feet. It can be measured using an Abney hand level, a hypsometer, a transit, a clinometer, a relascope, a laser or other instrument designed for that purpose.

Alternatively, you can use the stick method: Hold the stick at its base vertically, making certain that the length of the stick above your hand equals the distance from your hand to your eye. Staying on ground level (or on the same contour as the base of the tree), move away from the tree while sighting the trunk base above your hand. Stop when the top of the stick is level with the top of the tree. You should be looking over your hand at the base of the tree and, moving only your eyes, looking over the top of your stick at the top of your tree. Measure how far you are from the tree and that measurement - in feet - is the tree's height.

Calculating Total Points

Once all measurements are taken, the total points are calculated using the following formula:

Total Points = Circumference (Inches)
+ Total Tree Height (Feet)
+ $\frac{1}{4}$ of Average Crown Spread (Feet)
